

Probe report

This page is a **report**, not the experiment. The experiment in `experiment.py` resolves an activation cache that a *different* experiment (`docs/acts`) published to the project-scoped artifact store, summarizes it, and stores the summary as a durable artifact. Run both from the command line:

```
bin/mini run docs/acts/experiment.py --watch
bin/mini run docs/probe/experiment.py --watch
```

Here we read the durable summary back through its handle and render it. The figure is **externalized** to the artifact store (not inlined), so the published report stays light and the bytes are served from the bucket. The source links above are written *relative*; `build_site` resolves them to their GitHub source (a sibling report would resolve to its rendered page), so the only literal relative URLs left in the published report are its assets.

Probed **tiny-shakespeare** across **4** layers, reading activation bytes

8210278b656f... straight from the shared store – no recompute.
